Lecture 09: Reinforcement Learning overview and intro

Radoslav Neychev

Outline

- 1. Reinforcement Learning problem statement
- 2. (Multi-armed) bandits
- 3. MDP formalism
- 4. Relations to Psychology
- 5. Cross-entropy method
- 6. Reinforcement, Supervised and Unsupervised Learning

Reinforcement Learning problem statement

Supervised learning

Given:

Want them to be i.i.d. $x \in \mathcal{X}, y \in \mathcal{Y}$

- \circ Loss/objective function $L(\hat{y},y)$ Usually differentiable
- \circ Model family $f \in \mathcal{F}, f: \mathcal{X} \longrightarrow \mathcal{Y}$

Objects and reference answers

- Goal:
- $\circ \ \ \text{Find optimal mapping} \ f^* = \arg\min_{\mathbf{f}} L(f(x),y)_{_{_{\!\!\!4}}}$

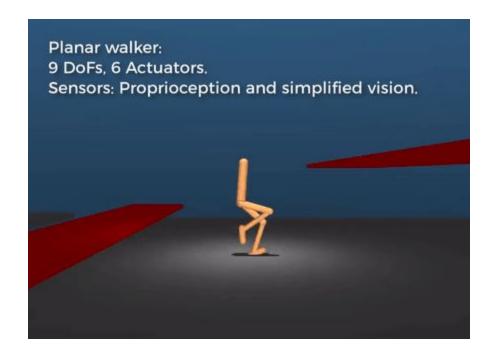

Reinforcement learning

 $x \in \mathcal{X}$

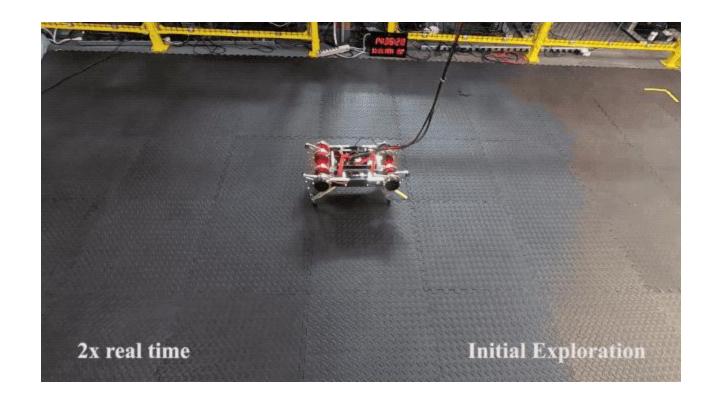

robot to walk

Given: Usually no reference answers
 E.g. want the

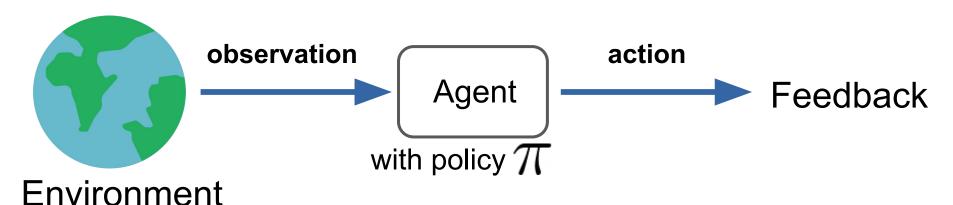

- Objects and reference answers
- $J \subset J$, $J \cdot I \subset J$
- Goal:
- $\circ~$ Find optimal mapping $f^* = \arg\min_{\mathbf{f}} L(f(x),y)_{_{\scriptscriptstyle{5}}}$

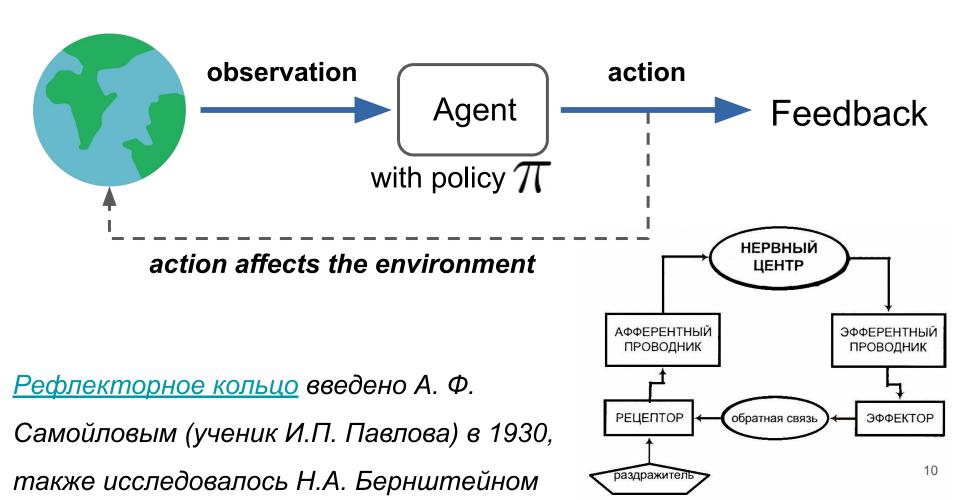

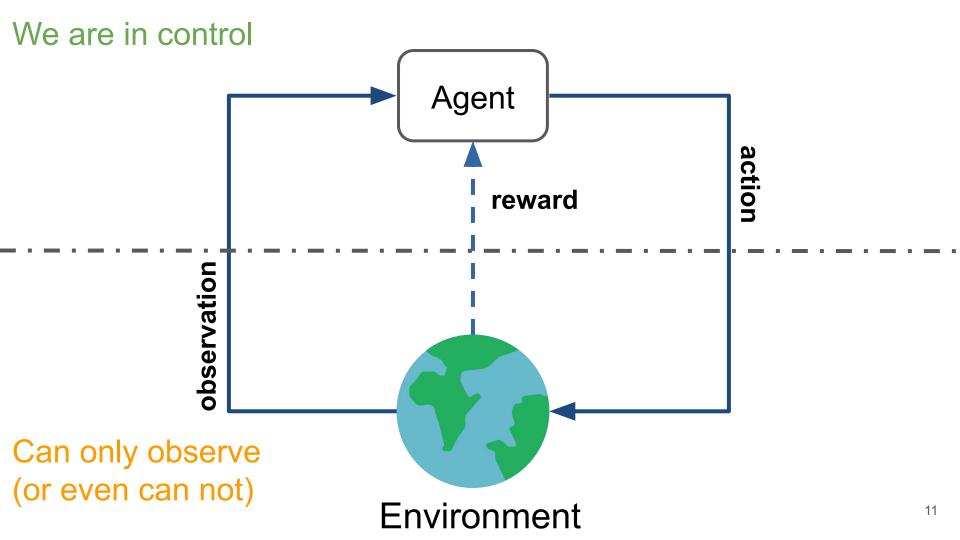

(Multi-armed) bandits

- Observation (state): vector or image or sequence ... or nothing
- Policy: mapping from state to action
- Action
- Feedback (reward): usually a converted to a number

Variety of papers on helicopter control: heli.stanford.edu

Andrew Y. Ng PhD Thesis link: <u>"Shaping and policy search in Reinforcement Learning"</u>

Reality check: dynamic control

- Observation: accelerometer, gyroscope, engine data
- Action: change rotation speed, angle
 - Feedback: some specific reward

source: heli.stanford.edu, photos by Ben Tse and Eugene Fratkin

- Observation: image(s)
- Action: move, fire, turn
- Feedback: score/health/progres/...

Open questions

- What is optimal action?
 - Maximize the reward on the next step
 - Maximize the reward in long term

Open questions

- Explore or exploit?
 - Stepping of current optimal strategy may decrease the cumulative reward
 - Under current optimal strategy one may never discover something better

 $a\in\mathcal{A}$ Reward: $r\in\mathbb{R}$

 $s \in \mathcal{S}$

State:

MDP formalism

• Dynamics: $P(s_{t+1}|s_t,a_t)$ S Environment $P(s_{t+1}|s_t,a_t)$

Markov property: $P(s_{t+1}|s_t,a_t,\ldots,s_0,t_0)=P(s_{t+1}|s_t,a_{t^{\scriptscriptstyle 16}})$

• Total reward for session: $R = \sum r_t$

• Policy:
$$\pi(a|s) = P(\text{take action } a \text{ in state } s)$$

• Goal: maximize reward; $\pi^*(a|s) = \arg\max_{\pi} \mathbb{E}_{\pi}[R]$

Pro 2.

Psychological point of view

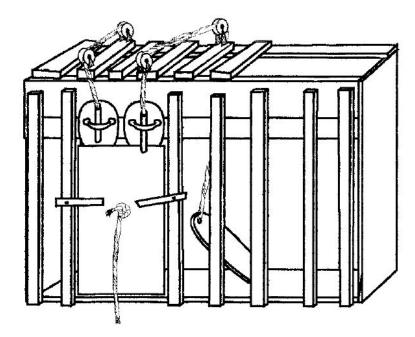

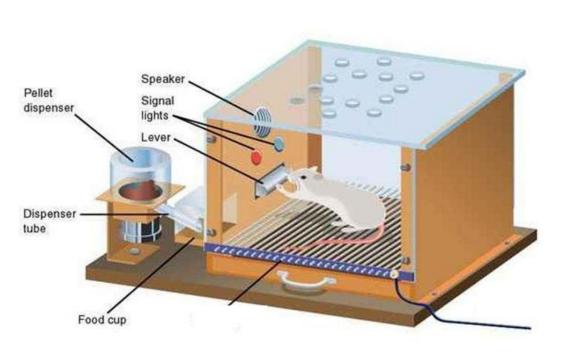

Fig. 4. Box K. The door is held in place by a weight suspended by a string. To open the door, a cat had to depress a treadle, pull on a string, and push a bar up or down. (After Thorndike, 1898, Figure 1, p. 8.)

Psychological point of view

CRAIG SWANSON @ WWW. PERSPICUITY. COM

How to maximize the reward?

 $\mathbb{E}_{\pi}[R]$ is an expected cumulative reward earned per session following policy π

Need to maximize the following objective:

$$\mathbb{E}_{\pi}[R] = \mathbb{E}_{s_0 \sim P(s_0)} \mathbb{E}_{a_0 \sim \pi(a|s_0)} \dots \mathbb{E}_{s_t, r_t \sim P(s, r|s_{t-1}, a_{t-1})}[r_0 + \dots + r_t]$$

How to do it?

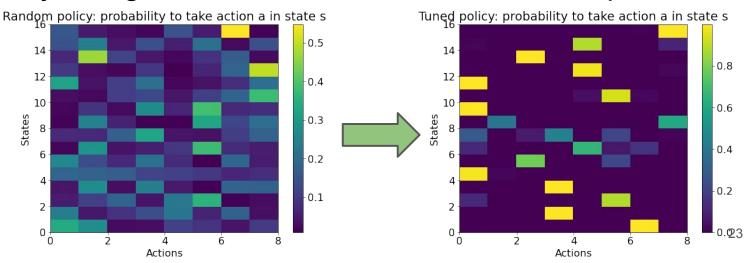

How to maximize the reward?

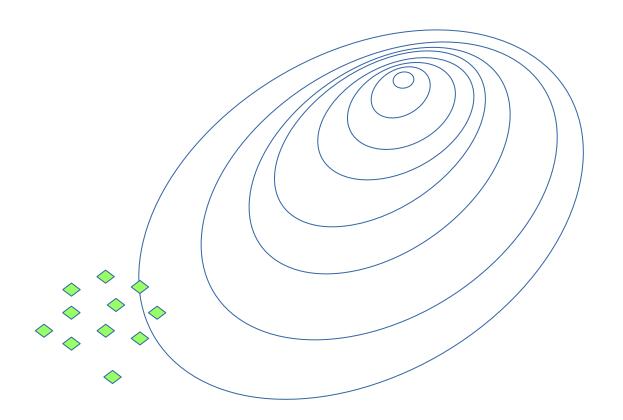

- Play a few sessions with existing policy
- Update the policy using new feedback
- Repeat

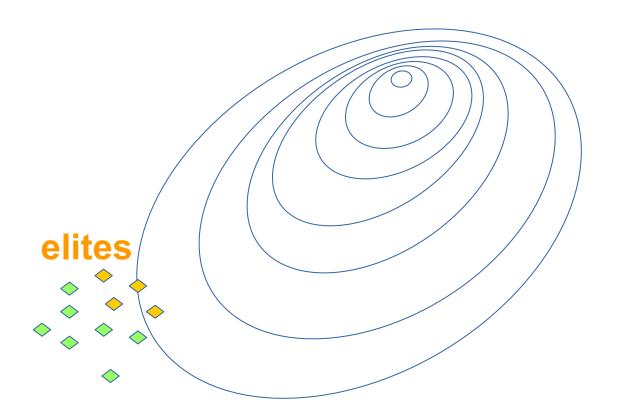

Cross-entropy method

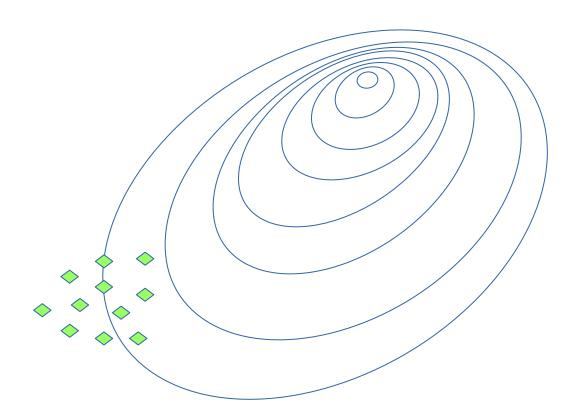

Cross-entropy method: tabular case

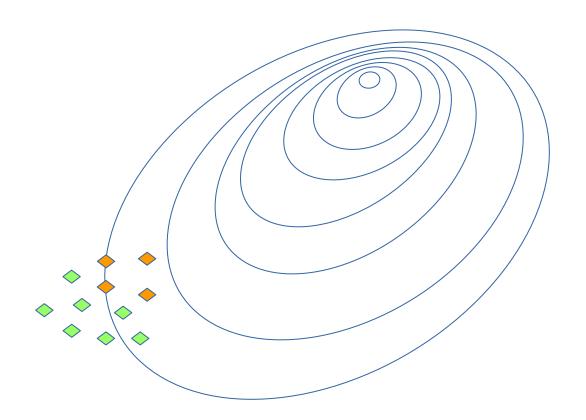

- Initialize policy (state-action matrix, every row sums up to 1)
- Sample N sessions
- Select M elite sessions with highest rewards
- Update policy using the elite session state-action sequences
- Repeat

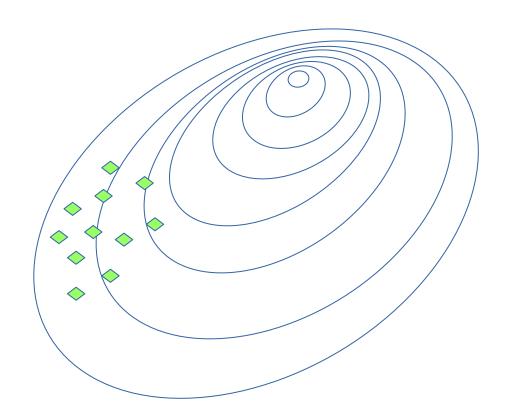

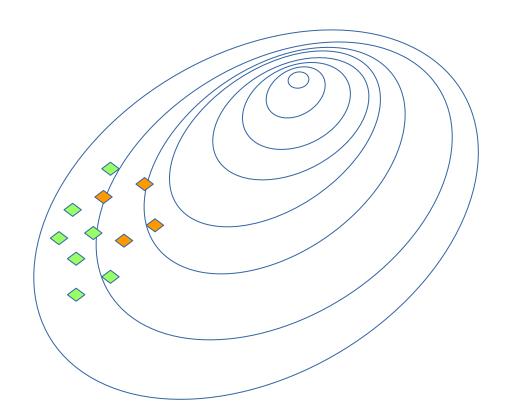

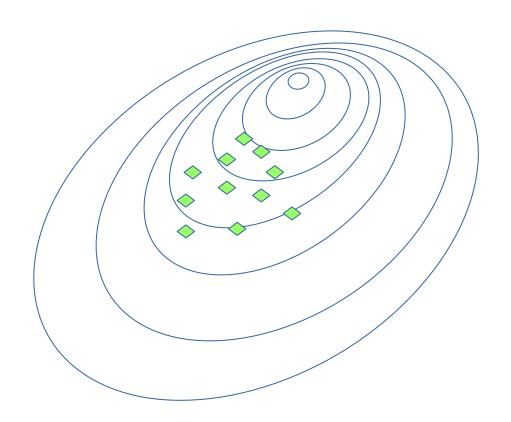

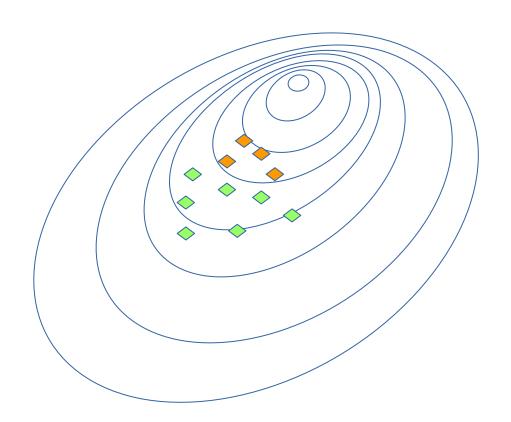

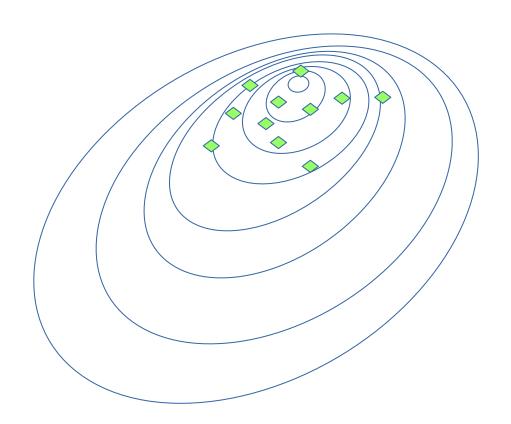

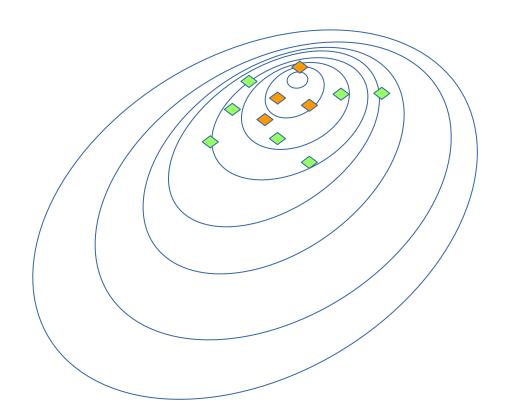

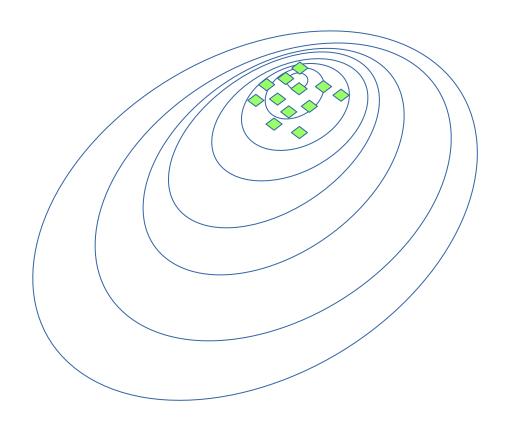

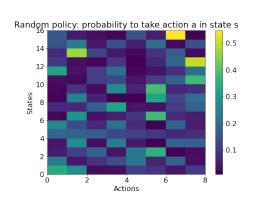

Cross-entropy method: tabular case

Policy is a matrix

$$\pi(a|s) = A_{s,a} \iff$$

- Sample N games with this policy
- Select M elite sessions with highest rewards

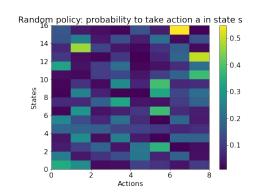

Elite =
$$[(s_0, a_0), (s_1, a_1), \dots, (s_M, a_M)]$$

• Update policy: $\pi_{\mathrm{new}}(a|s) = \frac{\sum\limits_{s_t, a_t \in \mathrm{Elite}} [s_t = s][a_t = a]}{\sum\limits_{s_t, a_t \in \mathrm{Elite}} [s_t = s]}$

Cross-entropy method: tabular case

Policy is a matrix

$$\pi(a|s) = A_{s,a} \iff$$

- Sample N games with this policy
- Select M elite sessions with highest rewards
- Update policy using the elite sessions:

$$\pi_{\text{new}}(a|s) = \frac{\text{how many times took action } a \text{ at state } s}{\text{how many times was at state } s}$$

Harsh reality

Some environments have huge or infinite number of states

How to fix it?

Approximate cross-entropy method

• Model (e.g. parametric) predicts action probability given state:

$$\pi(a|s) = f_{ heta}(a,s)$$
Random Forest Classifier,

model = RandomForestClassifier() Logistic Regression, NN etc.

Sample N sessions, select M elite sessions

model.fit(elite states, elite actions)

Elite =
$$[(s_0, a_0), (s_1, a_1), \dots, (s_M, a_M)]$$

New training set; states are objects,

Maximize likelihood of actions in elite sessions:

$$\pi(a|s)_{\text{new}} = \arg\max_{\pi} \sum_{i=1}^{\infty} \log \pi(a_i|s_i)$$

38

What if action space is continuous?

Approximate cross-entropy method

Model samples actions from some appropriate distribution:

$$\pi(a|s) = \mathcal{N}(\mu_{\theta}(a,s), \sigma_{\gamma}(a,s))$$
 One model Another model (or constant)

It is just a regressor!

What if action space Approximate cross-entropy method is continuous?

Model (e.g. parametric) predicts action given state:

```
model = RandomForestRegressor()
```

• Sample N sessions, select M elite sessions

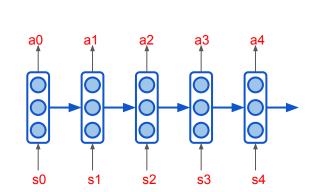

Elite =
$$[(s_0, a_0), (s_1, a_1), \dots, (s_M, a_M)]$$

Maximize likelihood of actions in elite sessions:

```
model.fit(elite states, elite actions)
```

Useful ideas

- Use elite sessions from several (3-5) past iterations for training
 - Experience from previous iterations is preserved
 - Convergence may be slower (e.g. on simple environments)
- Regularize the policy with entropy
 - Low entropy means weak exploration
- Sessions can be sampled in parallel
- Agent can use memory as well
 - We will meet RNNs again soon

Key differences

Key differences

Supervised Learning

- Learn to approximate reference answers
- Need reference answers
- Model does not affect the input data

Reinforcement Learning

- Learn optimal strategy by trial and error
- Need feedback on agent's actions
- Agent actions affect the environment (so the observations)

Key differences

Unsupervised Learning

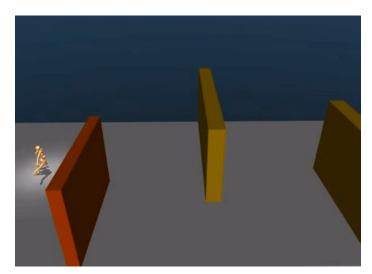

- Learn underlying data structure
- No feedback required
- Model does not affect the input data

Reinforcement Learning

- Learn optimal strategy by trial and error
- Need feedback on agent's actions
- Agent actions affect the environment (so the observations)

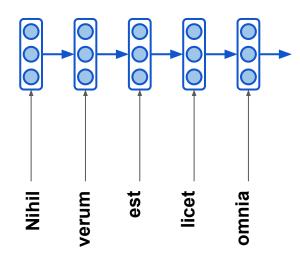

Outro

- RL is different both from Supervised and Unsupervised learning
- Reward formulation has huge effect on the agent behaviour
- Remember the Markov assumptions
- The cross-entropy method is simple and still very powerful approach
